

Lecture 38**1 Polynomial Rings****1.1 Notation and Terminology**

Definition 1 (Ring of Polynomials over R). *Let R be a commutative ring.*

$$R[x] = \{a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0 \mid a_i \in R, n \in \mathbb{Z}_{>0}\}$$

is called the ring of polynomials over R in the indeterminate x .

Addition and multiplication are as usual.

$$f = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0$$

If $a_n \neq 0$, then $\deg(f) = n$ and a_n is called the leading coefficient of f .

If $a_n \neq 0$ is the multiplicative identity of R , then f is called a monic polynomial.

a_0 is called the constant term of f .

If $f(x) = a_0$ then f is called a constant polynomial.

Theorem 1.1. *If D is an integral domain, then $D[x]$ is an integral domain.*

$$\text{Proof. } f(x) = a_n x^n + \underbrace{\quad \cdots \quad}_{\text{lower degree}}, \quad g(x) = a_m x^m + \underbrace{\quad \cdots \quad}_{\text{lower degree}}, \quad a_n \neq 0, a_m \neq 0 \in D$$

$$f(x) \cdot g(x) = (a_n \cdot a_m) x^{m+n} + \underbrace{\quad \cdots \quad}_{\text{lower degree}}$$

D integral domain $a_n \cdot a_m \neq 0$ $f(x) \cdot g(x) \neq 0$ since the leading term is nonzero. □

Theorem 1.2 (Division Algorithm for $F[x]$). *Let F be a field and $f(x), g(x) \in F[x]$ with $g(x) \neq 0$. Then there exists unique polynomials $q(x)$ and $r(x)$ in $F[x]$ such that*

$$f(x) = q(x)g(x) + r(x) \quad \text{and} \quad \text{either } r(x) = 0 \text{ or } \deg r(x) < \deg g(x)$$

Pf sketch.

- May assume $g(x)$ is monic ($F = \text{field}$).

$$\text{Say } g = x^n + a_{n-1} x^{n-1} + \cdots$$

- use x^n to “cancel” terms in $f(x)$

$$f(x) = b_m x^m + \cdots \text{ with } m \geq n$$

$$f(x) - b_m x^{m-n} \cdot g(x) = \text{polynomial of degree } < m$$

Then proceed by induction on degree. □

In $\mathbb{Z}_5[x]$,

$$f(x) = 3x^4 + x^3 + 2x^2 + 1$$

$$g(x) = x^2 + 4x + 2$$

$$\begin{array}{r}
 x^2+4x+2 \overline{) 3x^2+4x+1} \\
 \underline{3x^2+2x^2+0x+1} \\
 4x^3+x^2+0x+1 \\
 \underline{4x^3+x^2+3x} \\
 2x+1
 \end{array}
 \quad \left. \vphantom{\begin{array}{r} x^2+4x+2 \overline{) 3x^2+4x+1} \\ \underline{3x^2+2x^2+0x+1} \\ 4x^3+x^2+0x+1 \\ \underline{4x^3+x^2+3x} \\ 2x+1 \end{array}} \right\} \begin{array}{l} f(x) = g(x)(3x^2+4x+1) \\ + (2x+1) \\ \text{rcn} \end{array}$$

Corollary 1.3 (Remainder Theorem). *Let F be a field and $f(x) \in F[x]$. Then a is a zero of $f(x)$ $\iff x - a$ is a factor of $f(x)$*

Proof. $f(x) = (x - a)q(x) + r$ (where r is a constant)

$$\begin{aligned}
 a \text{ is a zero of } f &\iff f(a) = 0 \iff r = 0 \\
 &\iff f(x) = (x - a)q(x) \\
 &\iff (x - a) \text{ is a factor of } f
 \end{aligned}$$

□

Corollary 1.4 (Factor Theorem). *A polynomial of degree n over a field has at most n zeros counting multiplicity.*

Pf sketch. use Cor 16.2.1

□

Every polynomial in $\mathbb{C}[x]$ of deg n has exactly n zeros counting multiplicity.

Cor is not true for arbitrary polynomial rings.

$x^2 + 3x + 2$ in $\mathbb{Z}_6[x]$ has four zeros in \mathbb{Z}_6 (1, 2, 4, 5).

Definition 2 (Principal Ideal Domain (PID)). *A principal ideal domain (PID) is an integral domain R such that every ideal has the form $\langle a \rangle = \{ra \mid r \in R\}$ for some $a \in R$*

Theorem 1.5. *For any field F , $F[x]$ is a PID.*

Proof. Let I be an ideal in $F[x]$.

Assume $I \neq \{0\} = \langle 0 \rangle$

Let g be a polynomial in I that has minimum degree.

Then $I = \langle g(x) \rangle$ by the division algorithm

□

Theorem 1.6. \mathbb{Z} is a PID.

$\mathbb{Z}[x]$ is *not* a PID. (e.g. $\langle x, 2 \rangle$ is not principal)
